Ransomware Introduction

Ransomware is malware that infects computers, networks, and services

- Victim's computer is infected with malware
- Malware encrypts victim's data and/or systems, making them unreadable
- Actor demands payment to decrypt files or network
- Numerous variants and threat actor groups that launch the attacks

2

Ransomware Continues to Evolve

- **Ransomware-as-a-service:** business model where operators develop ransomware encryptor and supporting infrastructure (leak site; victim chat function) where affiliates launch the attacks with tools developed by the operator and they split the ransom payment.
 - Affiliates are moving between RaaS operators more frequently, complicating detection and response
- **Timed Wiper Malware:** threat actors install wiper malware before ransomware deployment and if payment is not made within the time the wiper malware is installed, it will execute to delete organization data. Increased pressure tactics from Threat Actor to force victim payments (e.g., DDoS attacks, shame sites, direct calls to employees) and increase in re-extortion after payment
- **Dual Ransomware attacks:** certain threat actors are launching multiple attacks after the first ransomware attack by a different ransomware variant to disrupt remediation efforts
- **Supply-Chain attacks:** Increased focus on targeting cloud infrastructure, managed services providers, industrial processes and software supply chain

3

Stages of Ransomware

4

Stages of Ransomware

- 5. Double Extortion**
Posting proprietary information to online marketplaces, only partially unlocking the system and demanding more money, simultaneously employing BEC

5

Common Traits: Ransom Page
